

**Name:** Oluwatamilore Deborah Akinleye

**School:** Silversands Hall School, Lekki

**Class:** JSS2

I wonder what the world would be like without the amazing efforts of Michael Faraday, Benjamin Franklin, William Gilbert, Thomas Edison, Nikola Tesla, George Westinghouse, and so. These fathers of electricity made significant contributions to the invention of electricity at various time intervals before arriving at what we have now. God in heaven has provided us with natural lighting, but imagine what the world would look like without electricity. There would be no means to provide lighting at night or in a dark environment, and no electricity to power television sets, refrigerators, fans, air conditioners, mobile phones, or even personal computers. Life would be so boring and things will be a lot harder than they currently are.

Life is relatively good because of the invention of electricity, and human beings around the world are enjoying a reasonable level of comfort because electricity provides a means to do so. However, as a Nigerian student living in this country, I feel there can be additional improvements to the current state of electricity that we have. Electricity is an invincible energy form that occurs in the universe and is generated by charged particles like electrons. These electrons are then passed as current through wires and cables, and this is what I feel should be improved upon.

Therefore, **if I could invent something new**, it would be **wireless electricity**—an electrical system accessible to people without wires and cables. My desire to invent wireless electricity is a result of the hardship and discomfort that come with the use of electricity during rainy seasons in Nigeria. Stormy weather often causes electrical poles to fall, destroying wires that are connected to them, thereby resulting in total blackouts for weeks or even months. The underground cable system is not by any means different. Large amounts of rainfall result in floods, causing the environment to become water-logged for weeks or months, and this is the reality for some of us who live on the island or in riverine environments.

The rate at which individuals become homeless may rise in the absence of wireless electricity because when wires come together, they may spark and cause houses to burn down, and they may not be able to rebuild. People who come into contact with open wires are at risk of electrocution if wireless electricity is not developed. However, the creation of wireless electricity will decrease the rate at which these accidents occur.

Wireless electricity will be of advantage to our society as it removes the dangers of sparks, electrocution, and fire outbreaks that come with wire and cable systems. There will be a decrease in expense because wireless electricity eliminates the need to repair worn-out sockets or cables.

All of the above are reasons wireless electricity should be invented, and it would be amazing because it only needs a transmitter to transfer electrical energy, not a physical wire connection.
